1 Algorithm Implementation

1.1 Code in Rust

The current OpenDP library contains the transformation make_bounded_sum_n implementing the bounded sum function with known n. This is defined in lines 53-68 of the file sum.rs in the Git repository¹ (https://github.com/opendp/opendp/blob/b936c74223b4e319 698fa51837b5f8f40f3126d3/rust/opendp/src/trans/sum.rs#L53-L68).

 $^{^{1}}$ As of July 1, 2021.

1.2 Pseudocode in Python

We present a simplified Python-like pseudocode of the Rust implementation below. The necessary definitions for the pseudocode can be found at "List of definitions used in the pseudocode".

Preconditions

To ensure the correctness of the output, we require the following preconditions:

• User-specified types:

- Variable n must be of type usize.
- Type T must have traits TotalOrd and Sub(Output=T).²

Postconditions

• A Transformation is returned (i.e., if a Transformation cannot be returned successfully, then an error should be returned).

```
def MakeBoundedSumN(L: T, U: T, n: usize):
      input_domain = SizedDomain(VectorDomain(IntervalDomain(L, U)), n)
      output_domain = AllDomain(T)
3
      input_metric = SymmetricDistance()
4
      output_metric = AbsoluteDistance(T)
5
6
      if L*n < get_min_value(T) or U*n > get_max_value(T):
          raise Exception('Invalid parameters')
9
      def Relation(d_in: u32, d_out: u32) -> bool:
10
          return d_out >= d_in*(U-L)/2
11
12
      def function(data: Vec(T)) -> T:
13
          return data.iter().sum()
14
      return Transformation(input_domain, output_domain, function,
      input_metric, output_metric, stability_relation)
```

2 Proof

2.1 Symmetric Distance

Theorem 1. For every setting of the input parameters (L, U, n) to MakeBoundedSumN, the transformation returned by MakeBoundedSumN has the following properties:

- 1. (Appropriate output domain). For every element v in $input_domain$, function(v) is in $output_domain$.
- 2. (Domain-metric compatibility). The domain input_domain matches one of the possible domains listed in the definition of input_metric, and likewise output_domain matches one of the possible domains listed in the definition of output_metric.

²For now, the OpenDP library only implements PartialOrd, but TotalOrd will soon be implemented.

3. (Stability guarantee). For every pair of elements v, w in $input_domain$ and for every pair (d_in, d_out) , where d_in is of type u32 and d_out is of type T, if v, w are d_{in} -close under $input_metric$ and $Relation(d_in, d_out) = True$, then function(v), function(v) are d_{out} -close under $output_metric$.

Proof. (Appropriate output domain). In the case of MakeBoundedSumN, this corresponds to showing that for every vector v in SizedDomain(VectorDomain(IntervalDomain (L, U)), n), where L and U have type T, then function(v) belongs to AllDomain(T). The output correctness follows from the type signature of function as defined in line 13 and from the overflow check in line 8. The latter ensures that function(v) is contained in the interval [get_min_value(T), get_max_value(T)], and hence no overflow occurs in line 14. The former automatically enforces that function(v) has type T. Since the Rust code successfully compiles, by the type signature the appropriate output domain property must hold. Otherwise, the code will raise an exception for incorrect input type.

(Domain-metric compatibility). For MakeBoundedSumN, this corresponds to showing that SizedDomain(VectorDomain(IntervalDomain (L, U)), n) is compatible with symmetric distance, and that AllDomain(T) is compatible with absolute distance. Both follow directly from the definition of symmetric distance and absolute distance (note that, for symmetric distance, SizedDomain(VectorDomain(D)) is a subset of VectorDomain(D), as stated in "List of definitions used in the proofs", along with the appropriate output domain property shown above, which ensures that output_domain is indeed AllDomain(T).

(Stability guarantee). Throughout the stability guarantee proof, we can assume that function(v) and function(w) are in the correct output domain, by the appropriate output domain property shown above.

Since by assumption Relation(d_in,d_out) = True, by the MakeBoundedSumN stability relation (as defined in line 10 in the pseudocode), we have that d_out \geq d_in \cdot (U - L)/2. Moreover, v, w are assumed to be d_in-close. By the definition of the symmetric difference metric, this is equivalent to stating that $d_{Sym}(v, w) = |\text{MultiSet}(v)\Delta \text{MultiSet}(w)| \leq \text{d_in.}$

Further, applying the histogram notation,³ it follows that

$$d_{Sym}(v,w) = \|h_v - h_w\|_1 = \sum_z |h_v(z) - h_w(z)| \le \mathtt{d}_-$$
in.

We want to show that

$$d_{Abs}(\texttt{function}(v),\texttt{function}(w)) \leq d_{Sym}(v,w) \cdot \frac{\texttt{U-L}}{2}.$$

This would imply that

$$d_{Abs}(\texttt{function}(v),\texttt{function}(w)) \leq d_{Sym}(v,w) \cdot \frac{\texttt{U-L}}{2} \leq \texttt{d_in} \cdot \frac{\texttt{U-L}}{2}, \tag{1}$$

and by the stability relation this will imply that

$$d_{Abs}(\text{function}(v), \text{function}(w)) \le d_{-}\text{out},$$
 (2)

as we want to see.
$$\Box$$

³See A Programming Framework for OpenDP, footnote 1 in page 3. Note that there is a bijection between multisets and histograms, which is why the proof can be carried out with either notion. For further details, please consult https://www.overleaf.com/project/60d214e390b337703d200982.

2.2 First proof: using the path property (adjacent pairs approach)

To show that $d_{Abs}(\texttt{function}(v), \texttt{function}(w)) \leq d_{Sym}(v, w) \cdot \frac{\texttt{U-L}}{2}$, we will use the three lemmas described in the section "The path property of symmetric distance on sized domains" from the document "List of definitions used in the proofs". With these three lemmas, which are applicable to MakeBoundedSumN because input_domain is a sized domain and input_metric is symmetric distance, it suffices to show the following: For all vectors $x, y \in \texttt{input_domain}$ such that $d_{Sym}(x, y) = 2$, it follows that

$$d_{Abs}(\mathtt{function}(x),\mathtt{function}(y)) \leq \mathtt{U} - \mathtt{L}.$$

By Lemma 3 from "List of definitions used in the proofs", we know that vectors x, y only differ on one element, given that, by assumption, $d_{Sym}(x, y) = 2$. Wlog, let this different element be the k-th element of x and y, where $x_k = \alpha$, $y_k = \beta$ with $\alpha \neq \beta$.⁴ Then,

$$d_{Abs}(\mathtt{function}(x),\mathtt{function}(y)) = |\mathtt{function}(x) - \mathtt{function}(y)| =$$

$$= \Big|\sum_{i=0}^{\mathsf{n}-1} x_i - \sum_{i=0}^{\mathsf{n}-1} y_i\Big| = \Big|\sum_{i=0}^{\mathsf{n}-1} (x_i - y_i)\Big| = |\alpha - \beta| \leq |\mathtt{U-L}| = \mathtt{U-L},$$

since $\mathtt{U} \geq \mathtt{L}$. Therefore, applying Lemma 4 from "List of definitions used in the proofs", it follows that function is $(\mathtt{U}-\mathtt{L})/2$ -stable. By definition, this implies that for any $v,w \in \mathtt{input_domain}$,

$$d_{Abs}(\text{function}(v), \text{function}(w)) \le d_{Sym}(v, w) \cdot (\text{U-L})/2.$$

Lastly, by Equations 1 and 2 this implies that

$$d_{Abs}(function(v), function(w)) \leq d_{-}out,$$

as we want to prove.

2.3 Second proof: direct method (all pairs approach)

2.3.1 General inequality

The general statement that we will need to prove is the following. For any elements $a_1, \ldots, a_n \in [L, U]$ and b_1, \ldots, b_n ,

$$\left| \sum_{i} a_i b_i \right| \le \frac{a_{\text{max}} - a_{\text{min}}}{2} \cdot \left(\sum_{i} |b_i| \right).$$

Note that this corresponds to the tightest possible [L, U] interval.

Let u denote the vector formed by all the elements of v and w without multiplicities (i.e., u contains exactly once each of the elements in MultiSet(v) \cup MultiSet(w), in any order). Let u_i denote the i-th element of u, and similarly for v and w, and let m denote len(u). Then, by definition,

$$d_{Sym}(v, w) = \sum_{z} |h_v(z) - h_w(z)| = \sum_{i} |h_v(u_i) - h_w(u_i)|;$$

 $^{^4}$ The first element of a vector is indexed by 0.

$$\begin{split} d_{Abs}(\texttt{function}(v), \texttt{function}(w)) &= \Big| \texttt{function}(v) - \texttt{function}(w) \Big| = \Big| \sum_i v_i - \sum_i w_i \Big| = \\ &= \Big| \sum_i u_i \cdot h_v(u_i) - \sum_i u_i \cdot h_w(u_i) \Big| = \Big| \sum_i u_i \cdot (h_v(u_i) - h_w(u_i)) \Big|. \end{split}$$

Because by assumption $v, w \in \text{input_domain} = \text{SizedDomain}(\text{VectorDomain}(\text{IntervalDomain}(L, U)), n), we know that <math>\text{len}(v) = \text{len}(w) = n$. Therefore,

$$\sum_{i} (h_v(u_i) - h_w(u_i)) = \mathbf{n} - \mathbf{n} = 0.$$
(3)

We now separate the positive values from the negative ones by defining vectors x, y, λ and μ as follows. Let

$$h_v(u_{k_1}) - h_w(u_{k_1}) \le \ldots \le 0 \le h_v(u_{k_m}) - h_w(u_{k_m})$$

be the sequence of the $\{h_v(u_i) - h_w(u_i)\}$ in increasing order. Let s be the smallest value such that $h_v(u_{k_s}) - h_w(u_{k_s})$ is greater or equal to 0 (we set t = m if all the values are negative). Then, we define the vector entries of x, y, λ, μ as

$$x_j = h_v(u_{k_j}) - h_w(u_{k_j}),$$
$$\lambda_j = u_j,$$

for $s \leq j \leq m$, and

$$y_j = h_v(u_{k_j}) - h_w(u_{k_j}),$$
$$\mu_j = u_j$$

for $0 \le j < s$.⁵ That is, x contains all of the positive values and y all of the negative ones. Let r denote the length of vectors x and λ as constructed above, and by construction s denotes the length of vectors y and μ above (where r + s = m). Hence we obtain the values $x_1, \ldots, x_r \ge 0$ and $y_1, \ldots, y_s \le$ for some $r, s \in \mathbb{Z}$, such that

$$\sum_{i} x_i + \sum_{j} y_j = 0 \quad \text{and so} \quad \sum_{i} x_i = \sum_{j} |y_j|,$$

by Equation 3. Then,

$$\begin{split} d_{Abs}(\text{function}(v), \text{function}(w)) &= \Big| \sum_i u_i \cdot (h_v(u_i) - h_w(u_i)) \Big| = \\ &= |\lambda_1 x_1 + \dots + \lambda_r x_r + \mu_1 y_1 + \dots \mu_s y_s| = \Big| \overline{\lambda} \sum_i x_i + \overline{\mu} \sum_j y_j \Big| = \\ &= \frac{|\overline{\lambda} - \overline{\mu}|}{2} \Big(\sum_i x_i + \sum_j |y_j| \Big) = |\overline{\lambda} - \overline{\mu}| \sum_i x_i, \end{split}$$

where

$$\overline{\lambda} = \frac{\sum \lambda_i x_i}{\sum x_i}, \quad \overline{\mu} = \frac{\sum \mu_j y_j}{\sum y_j} = \frac{\sum \mu_j |y_j|}{\sum |y_j|};$$

⁵It is not necessary that the entries of x_j and y_j are ordered; only that they only contain positive and negative values, respectively, and that the λ and μ values match their corresponding indices.

i.e., they correspond to the weighted arithmetic mean.

By definition of the input_domain, the entries of v and w are contained within the interval [L, U], and hence $U \ge \max\{\lambda_i, \mu_j\}$ and $L \le \min\{\lambda_i, \mu_j\}$. Then,

$$\frac{\operatorname{U-L}}{2} \Big(\sum_i x_i + \sum_j |y_j| \Big) = \frac{\operatorname{U-L}}{2} \cdot 2 \sum_i x_i = (\operatorname{U-L}) \sum_i x_i.$$

Since $|\overline{\lambda} - \overline{\mu}| \le \mathtt{U-L}$, it follows that

$$d_{Abs}(\mathtt{function}(v),\mathtt{function}(w)) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i + \sum_j |y_j| \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_j \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i x_i - \sum_j y_i \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \Big($$

$$\frac{\overline{\lambda} - \overline{\mu}}{2} \Big(\sum_i |h_v(u_i) - h_w(u_i)| \Big) = \frac{\overline{\lambda} - \overline{\mu}}{2} \cdot d_{Sym}(v, w) \leq \frac{\mathtt{U-L}}{2} \cdot d_{Sym}(v, w).$$

Hence,

$$d_{Abs}(\texttt{function}(v),\texttt{function}(w)) \leq \frac{\texttt{U-L}}{2} \cdot d_{Sym}(v,w),$$

as we wanted to show.
